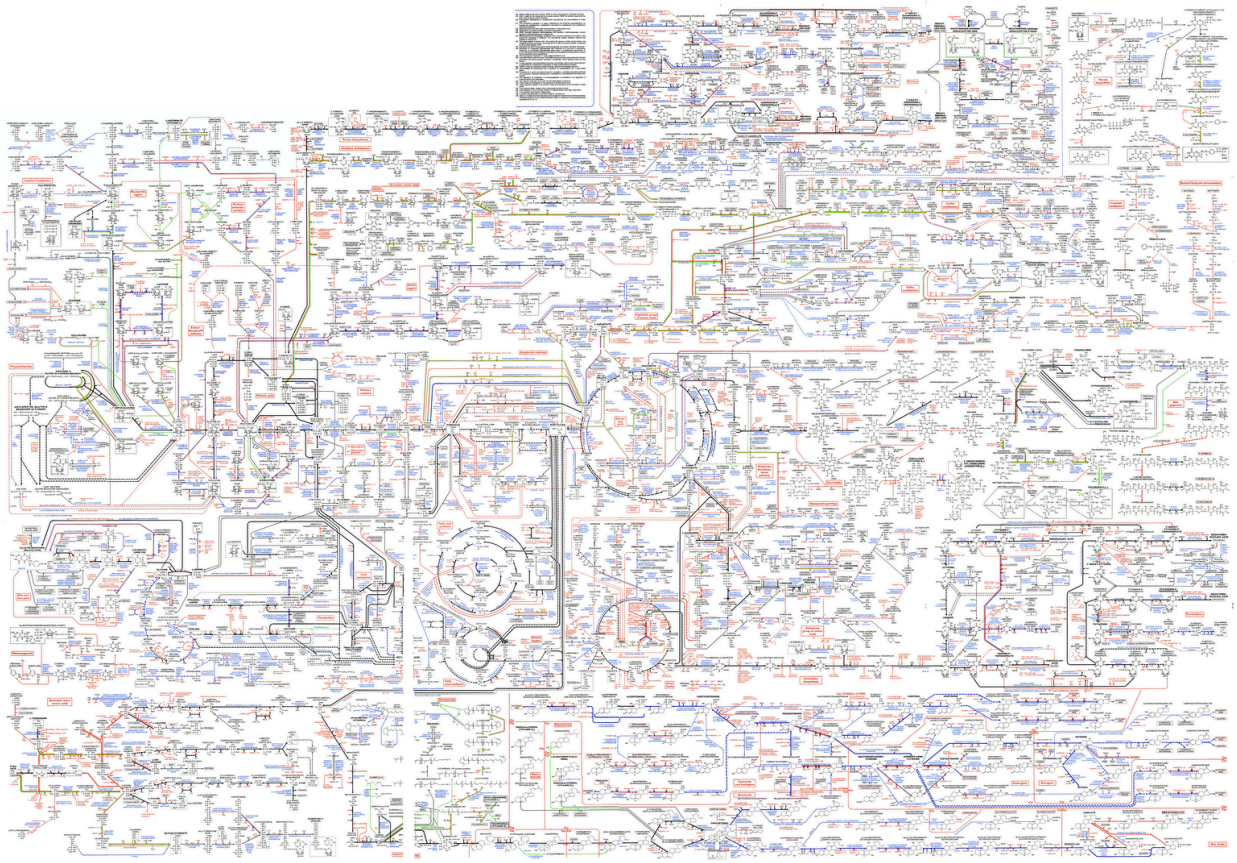
The Organic Chemistry of Life

The famous poster "Biochemical Pathways" by G. Michal:



Every biological process involves the making and breaking of chemical bonds; these are *chemical transformations* (mostly organic chemistry)!

How is organic chemistry in the cell different from organic chemistry in the lab?

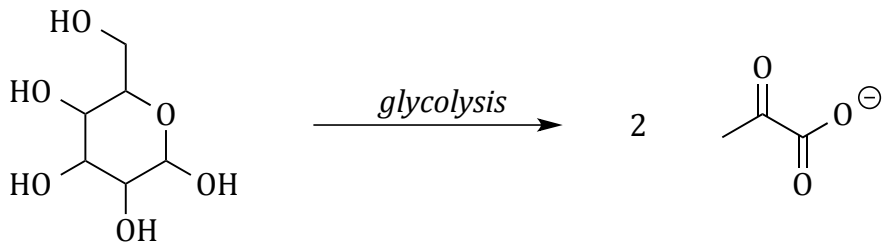
Enzymes: millennium-old organic chemist w/ really tiny fingers!

Enzymes: lower E T.S. (lower E_a) and change mechanisms (lower E of intermediates) providing H^+ wherever needed

The Organic Chemistry of Life:
Bread and Beer

Nearly all organisms get energy from *glycolysis*, the transformation of glucose into pyruvate:

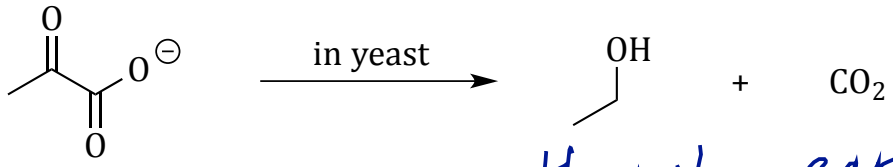
6 carbon



3 carbon

glucose pyruvate

In yeast, pyruvate is converted to ethanol and carbon dioxide:



ethanol carbon dioxide

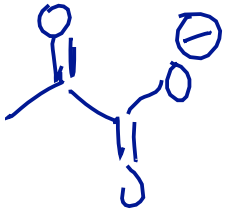
What use does the yeast have for ethanol and CO_2?

Waste, no use

What use do *we* have for ethanol and CO_2?

beer, wine, bread

How might the yeast accomplish this transformation?

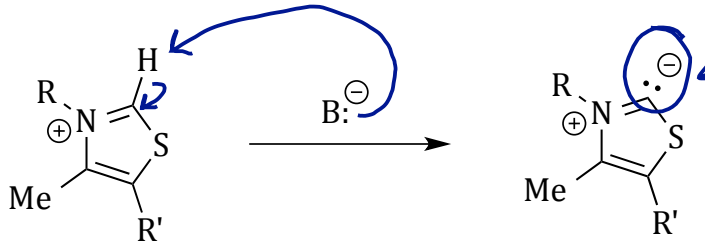


β-ketoacids?

α-ketoacid ~ can't decarboxylate

The Organic Chemistry of Life:
Bread and Beer: CO_2

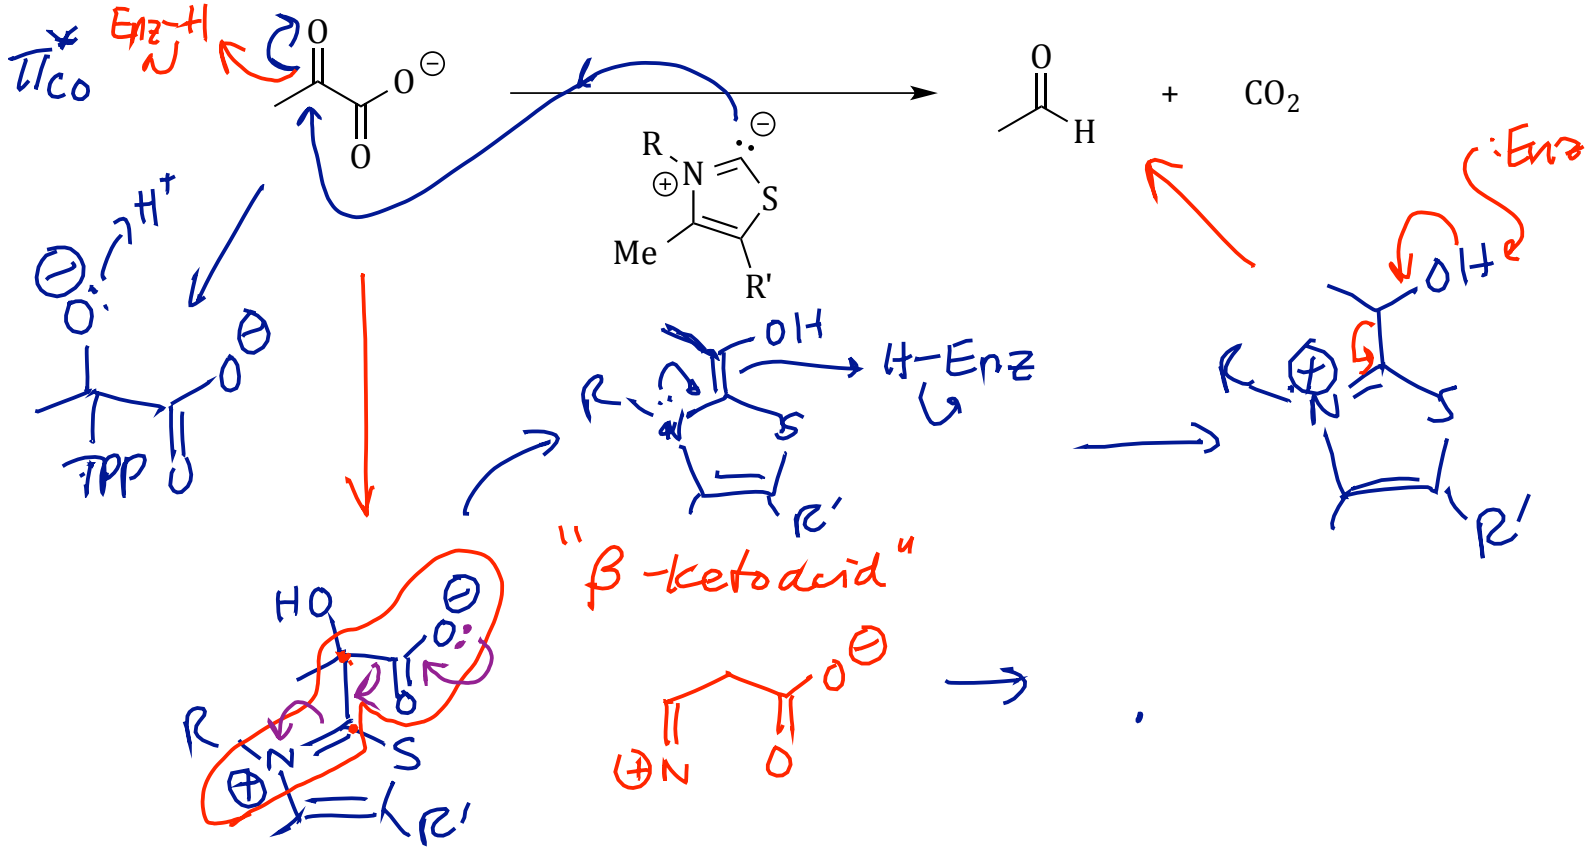
The decarboxylation of pyruvate requires thiamine as a *cofactor*, in the form of a thiamine diphosphate (TPP) ylide:



TPP (thiamine diphosphate) — TPP ylide

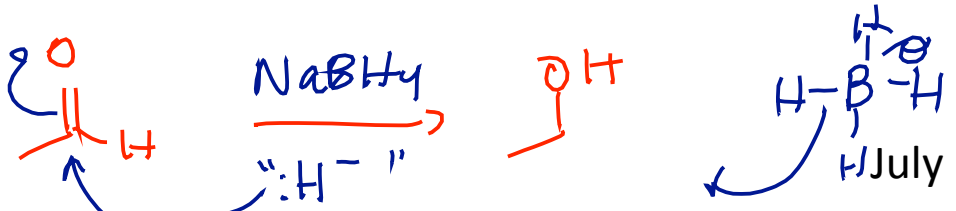
adj. opp/charges

Show how the TPP ylide can catalyze the decarboxylation of pyruvate. This reaction is the source of the CO_2 that makes bread rise and makes beer bubbly.



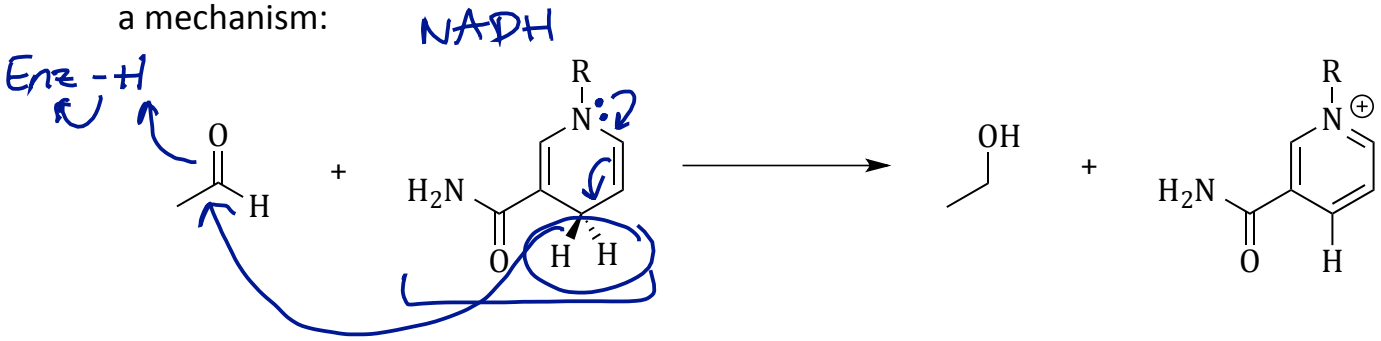
Note how the TPP ylide turns a tough α-decarboxylation into an easy β-decarboxylation!

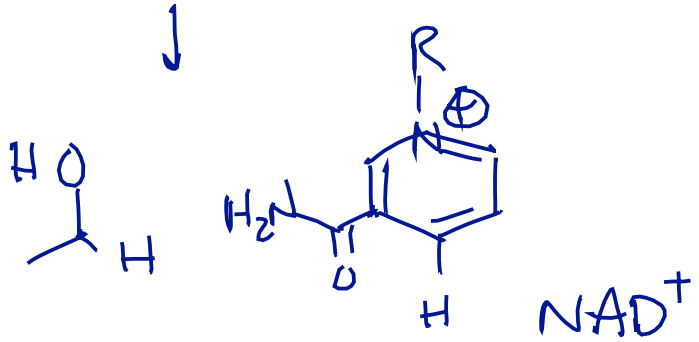
TPP ylide



The Organic Chemistry of Life:
Bread and Beer: Ethanol

The transformation of acetaldehyde into ethanol requires the cofactor NADH. Propose a mechanism:



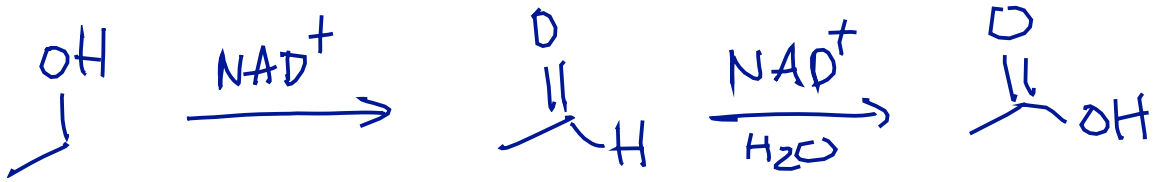


biochemical reduction of carbonyl

What is the "orgo lab" equivalent of NADH?

NaBH4 (or LiAlH4)

The *reverse* process – oxidation of ethanol to acetaldehyde – is catalyzed by an enzyme in your liver, *liver alcohol dehydrogenase* (LADH). This enzyme requires the cofactor NAD^+. Why? What is the "orgo lab" equivalent of NAD^+?

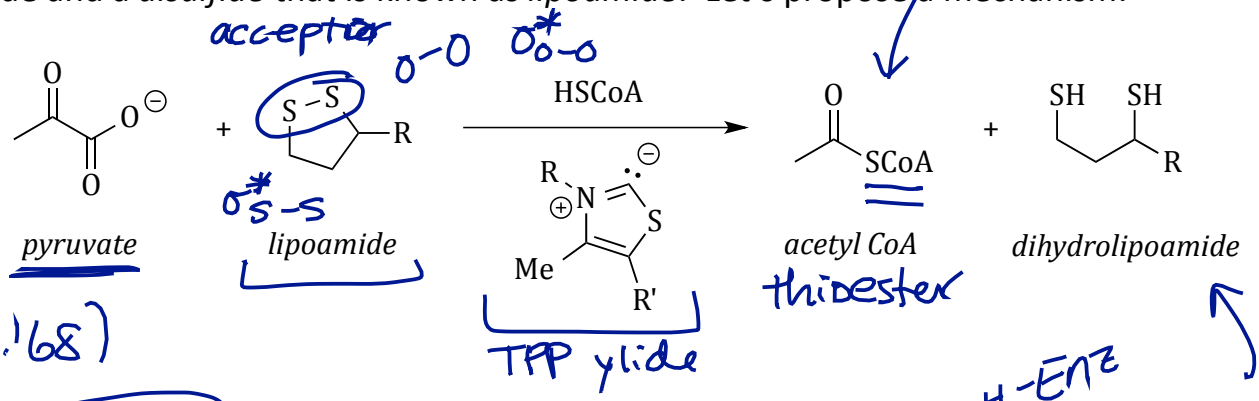


liver alcohol ~~aldehyde~~ dehydrogenase — slow

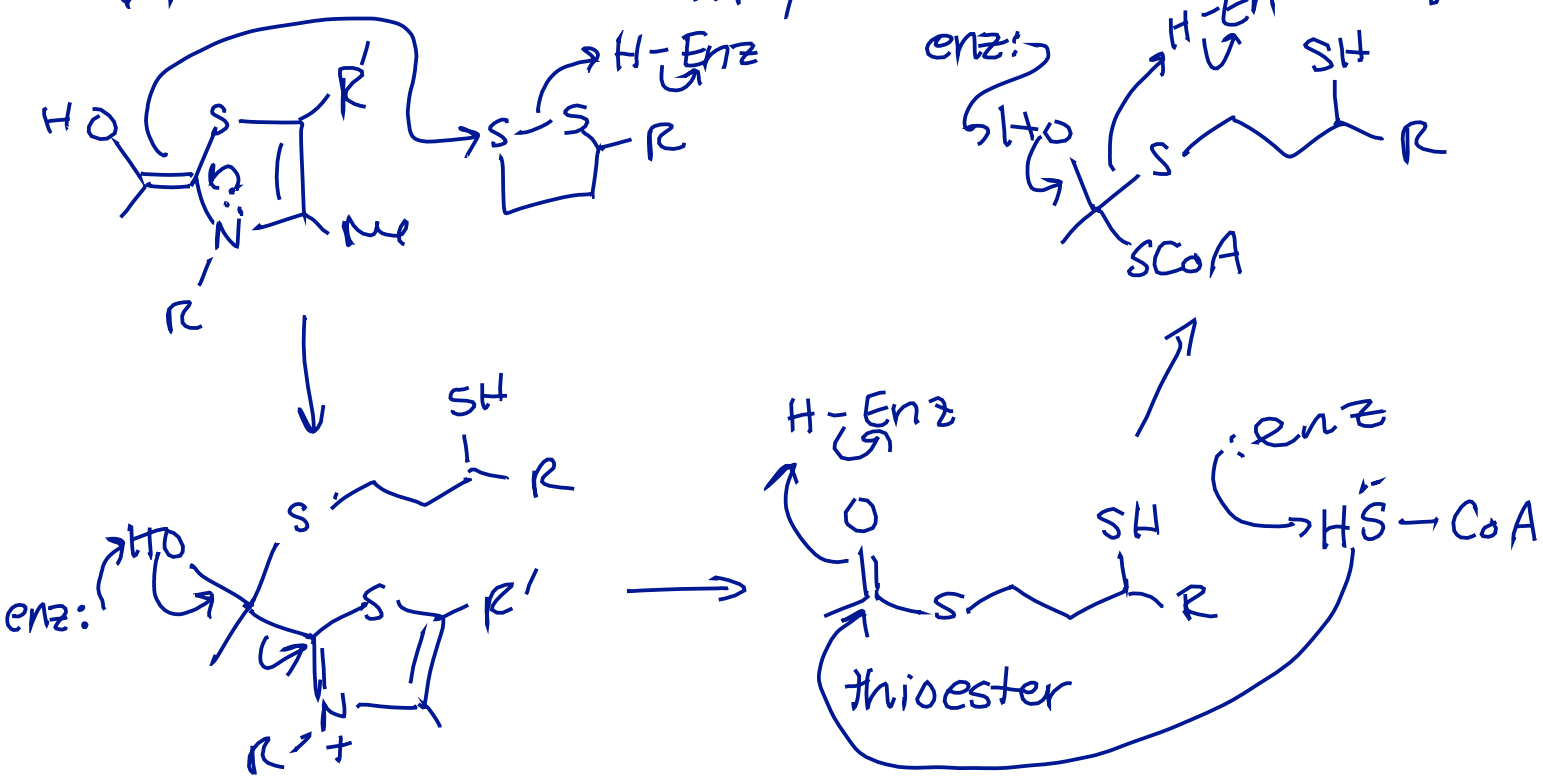
liver aldehyde dehydrogenase — slow

The Organic Chemistry of Life:
Biosynthesis of Acetyl CoA

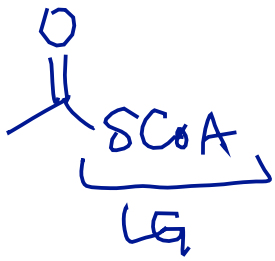
Pyruvate is also the source of *acetyl coenzyme A*, a thioester that is the crucial building block for a huge number of biomolecules. The overall transformation involves the TPP ylide and a *disulfide* that is known as *lipoamide*. Let's propose a mechanism:

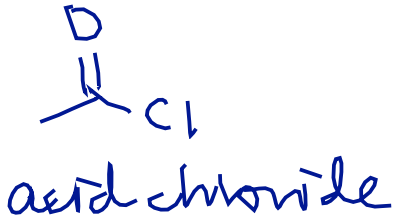


$-CO_2$ (p. 168)



Why are thioesters like acetyl CoA so useful in biological systems?





transthioesterification

TPP ylide, NADH (reducing), NAD^+ (oxidizing)

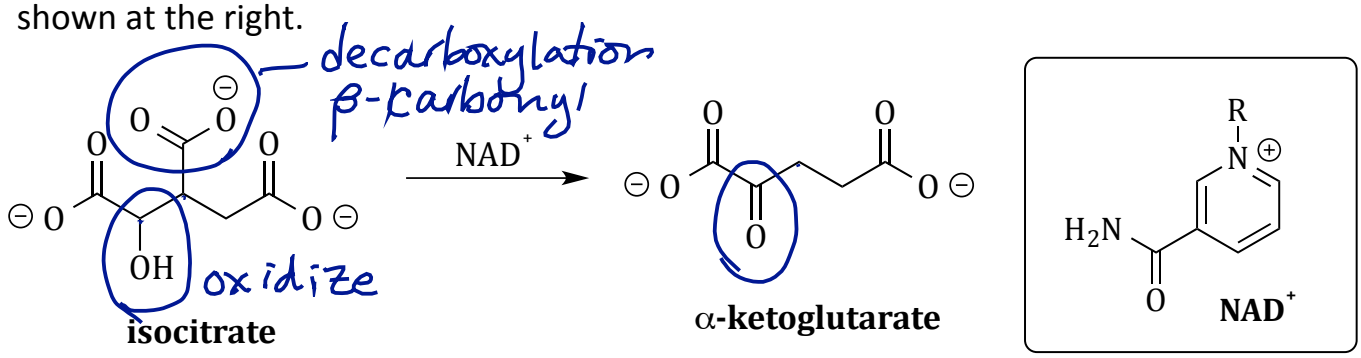
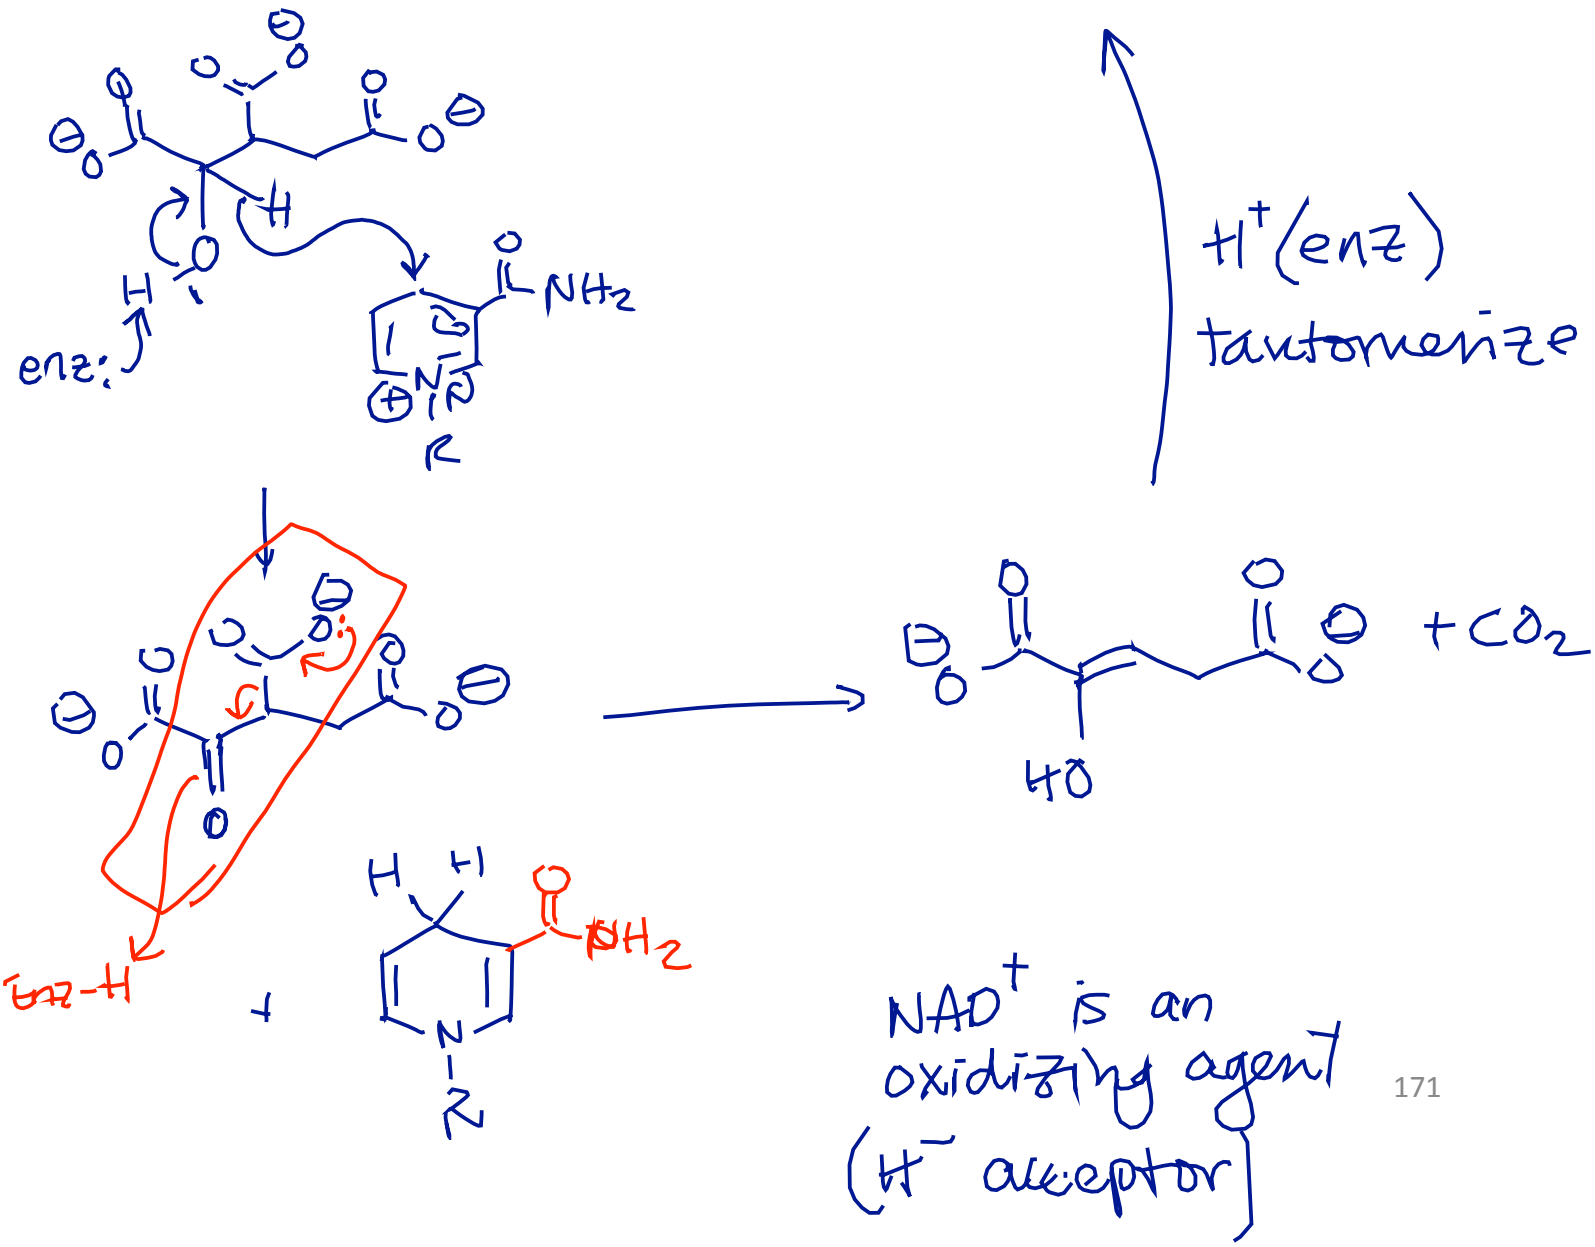
The Organic Chemistry of Life:
Test Yourself Now!

Provide a complete curved-arrow mechanism for the following biochemical transformation, which is part of the citric acid (Krebs) cycle. Structures of cofactors are shown at the right.

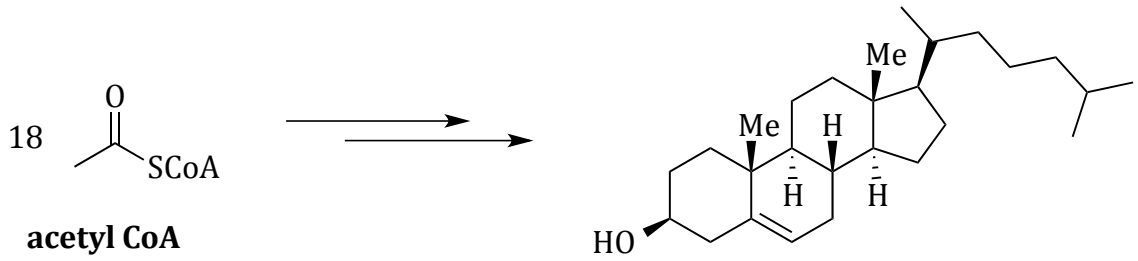




NAD^+ is an oxidizing agent (H^- acceptor)

The Organic Chemistry of Life:
Cholesterol Biosynthesis

Acetyl CoA is the starting material for the biosynthesis of cholesterol. Propose a complete curved-arrow mechanism for this transformation:

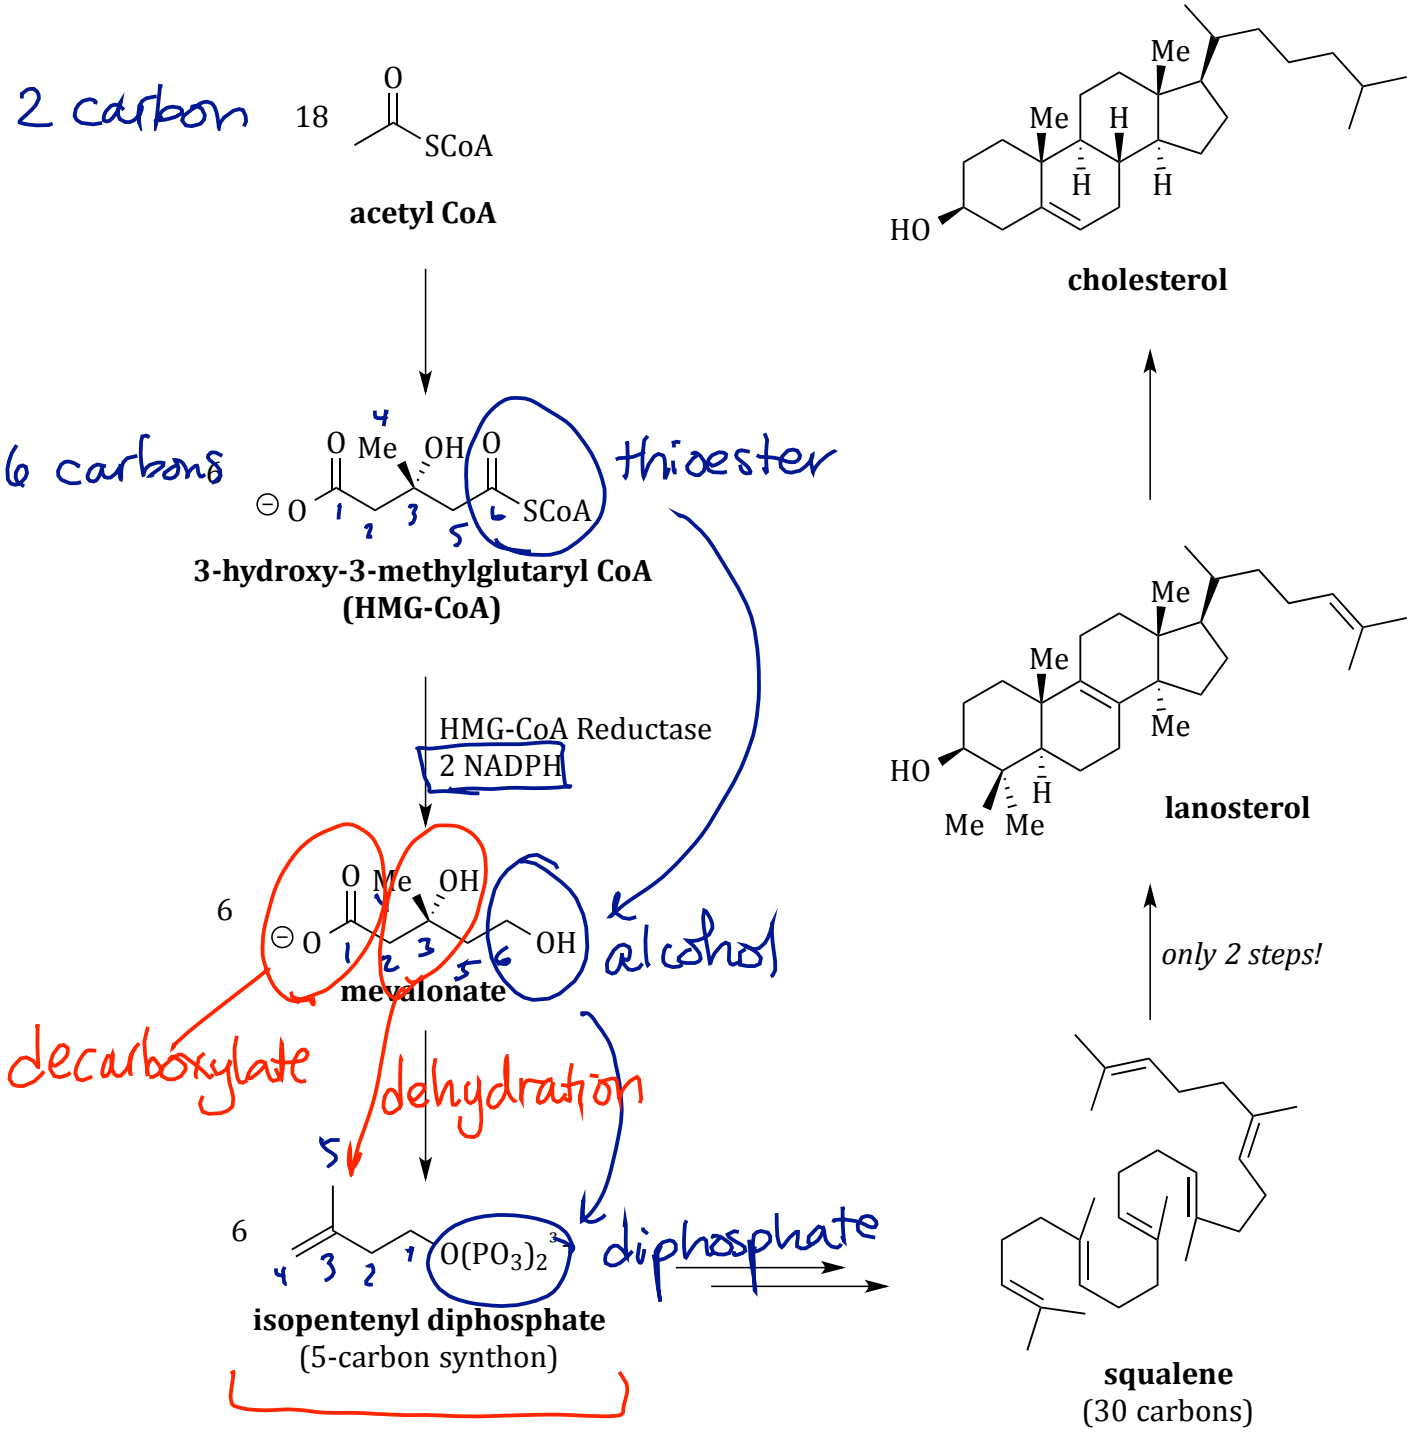


acetyl CoA **cholesterol**

Don't!

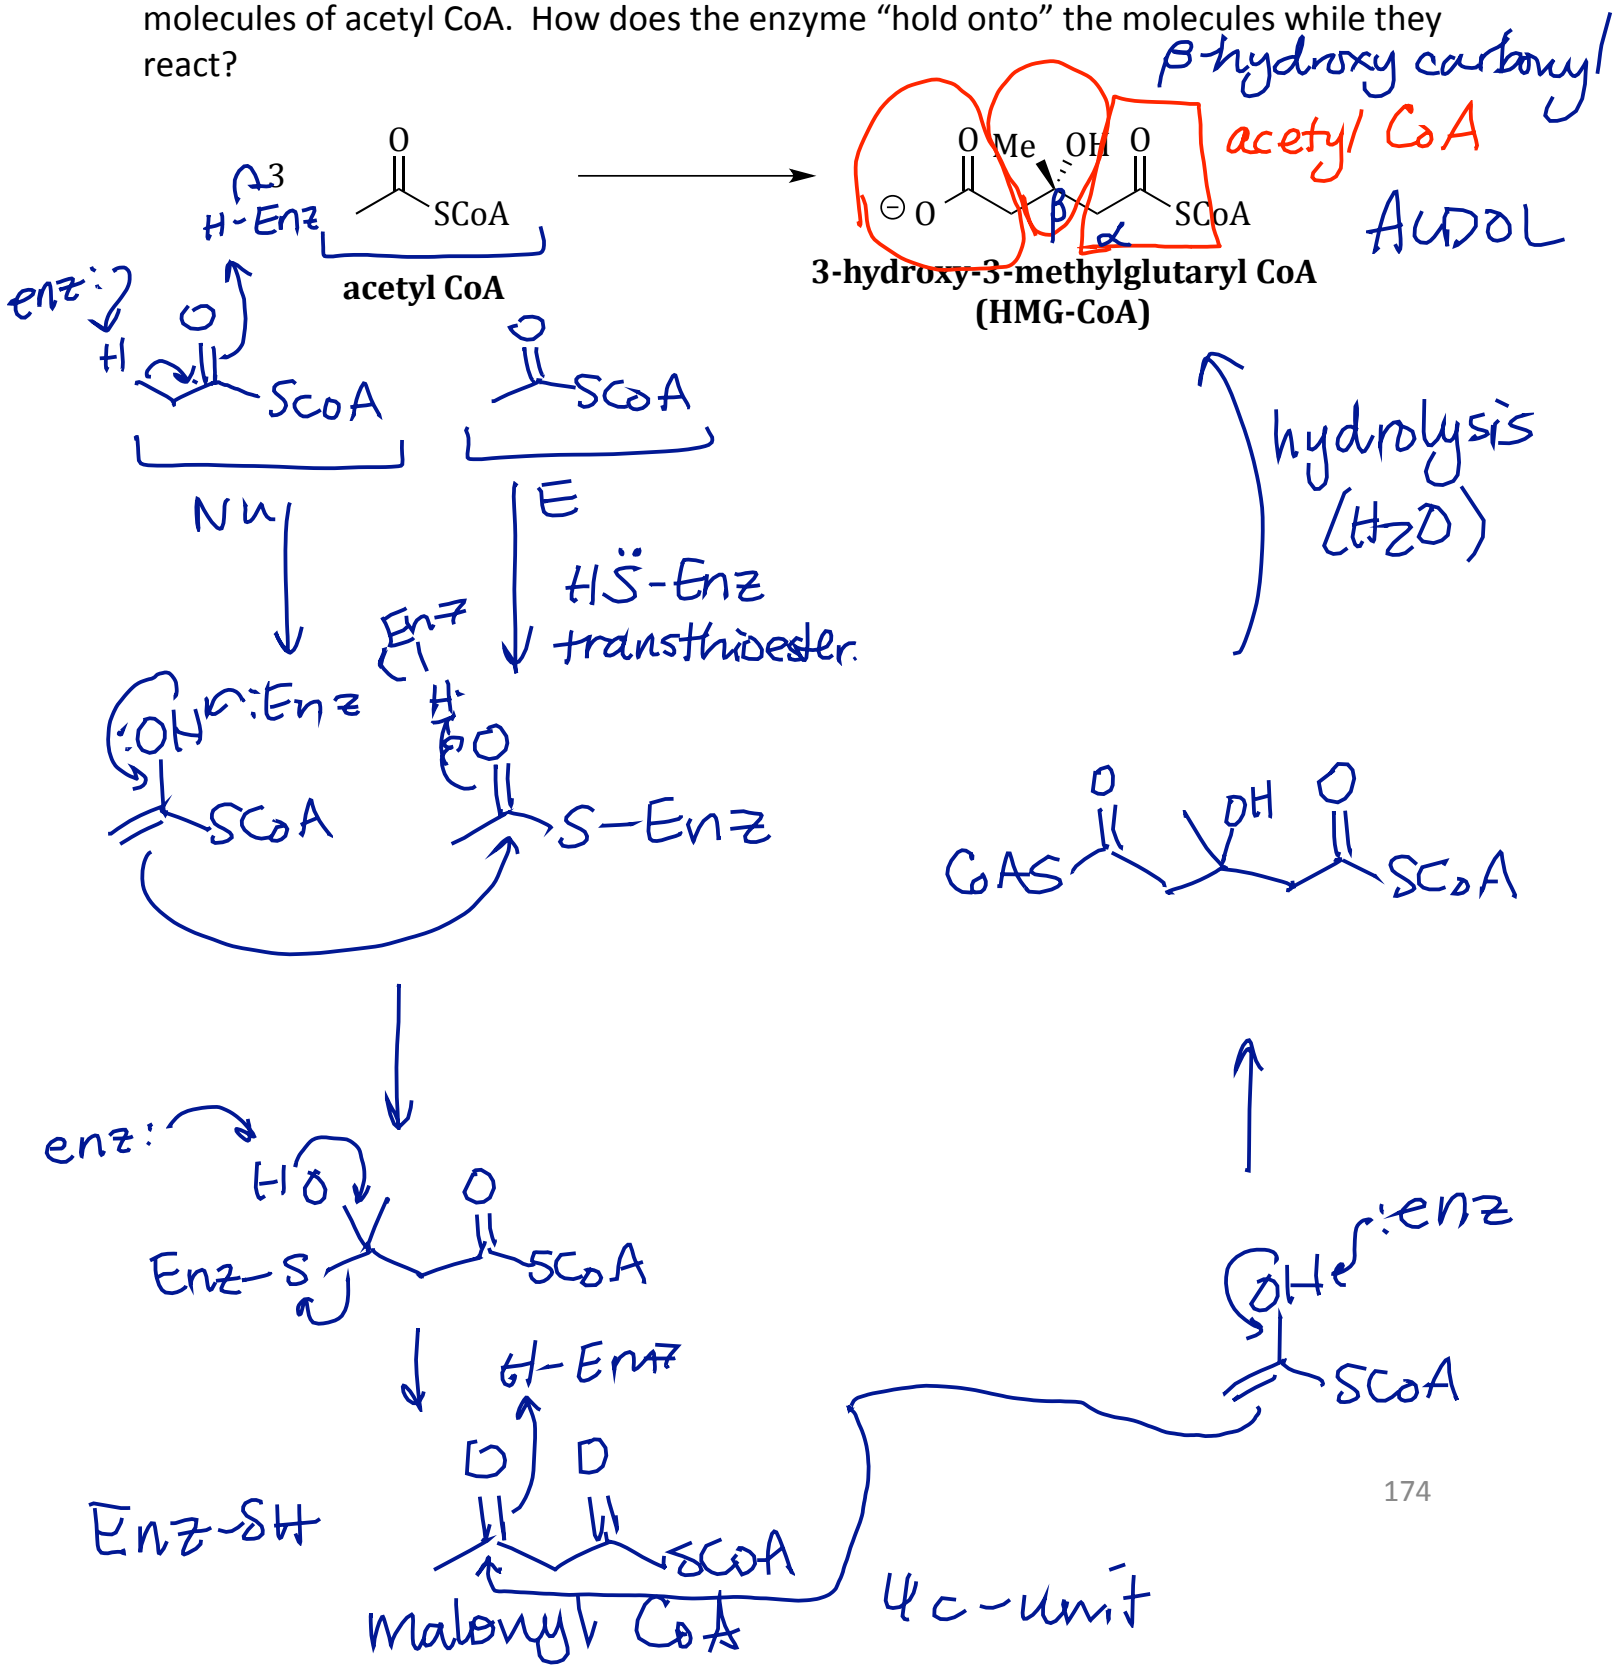
Cholesterol Biosynthesis:
Overview

Here are the **big steps** involved in cholesterol biosynthesis:



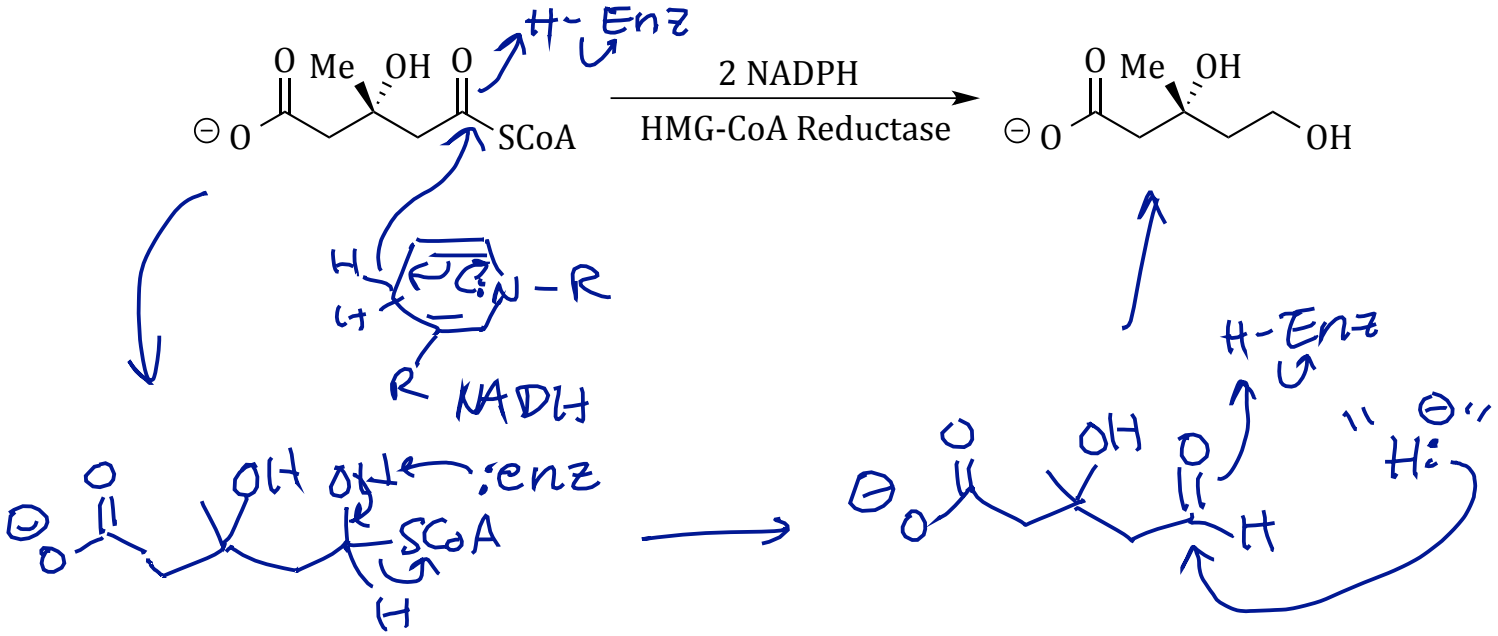
Cholesterol Biosynthesis:
1) Synthesis of HMG-CoA

Provide a complete curved-arrow mechanism for the synthesis of HMG-CoA from three molecules of acetyl CoA. How does the enzyme "hold onto" the molecules while they react?



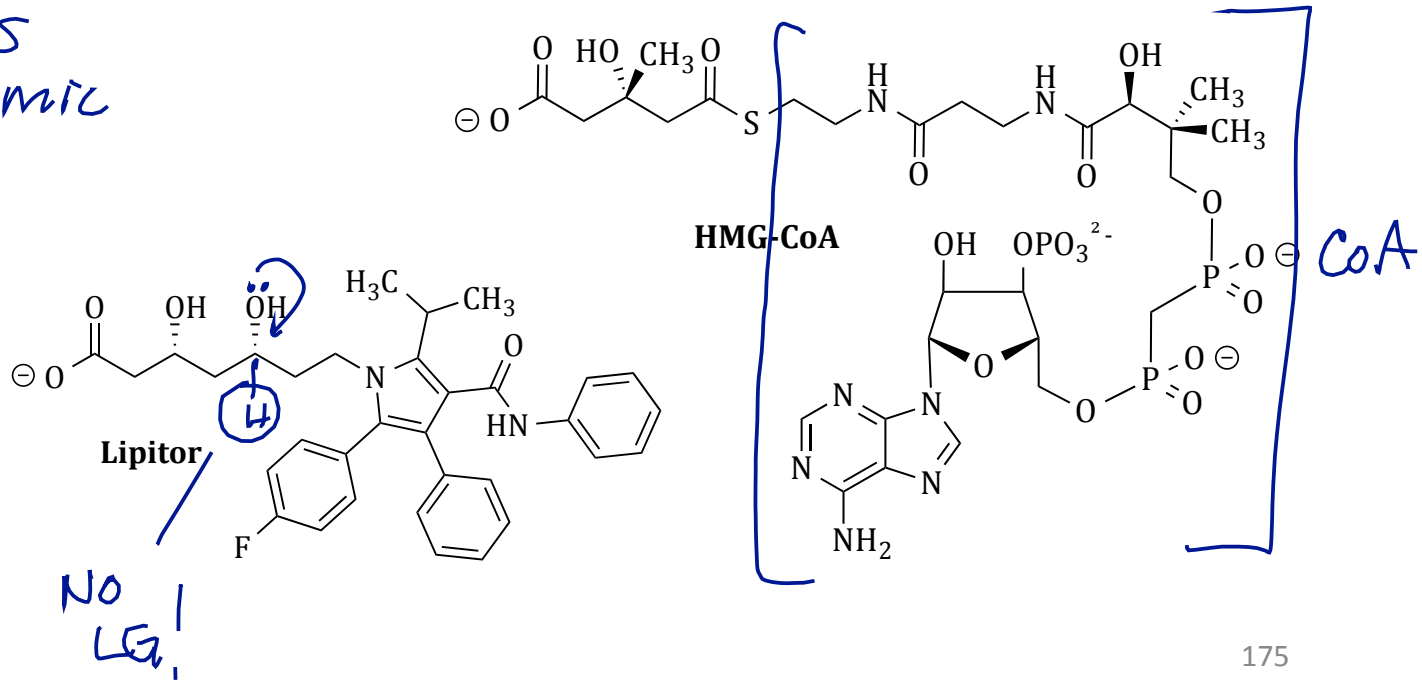
Cholesterol Biosynthesis:
2) HMG-CoA Reductase: Targeted by Statins

The remarkable anti-cholesterol drugs known as *statins* target the next step of cholesterol biosynthesis: the reduction of HMG-CoA to mevalonate. Provide a mechanism for this reaction. Are there any *cofactors* involved in this reaction?



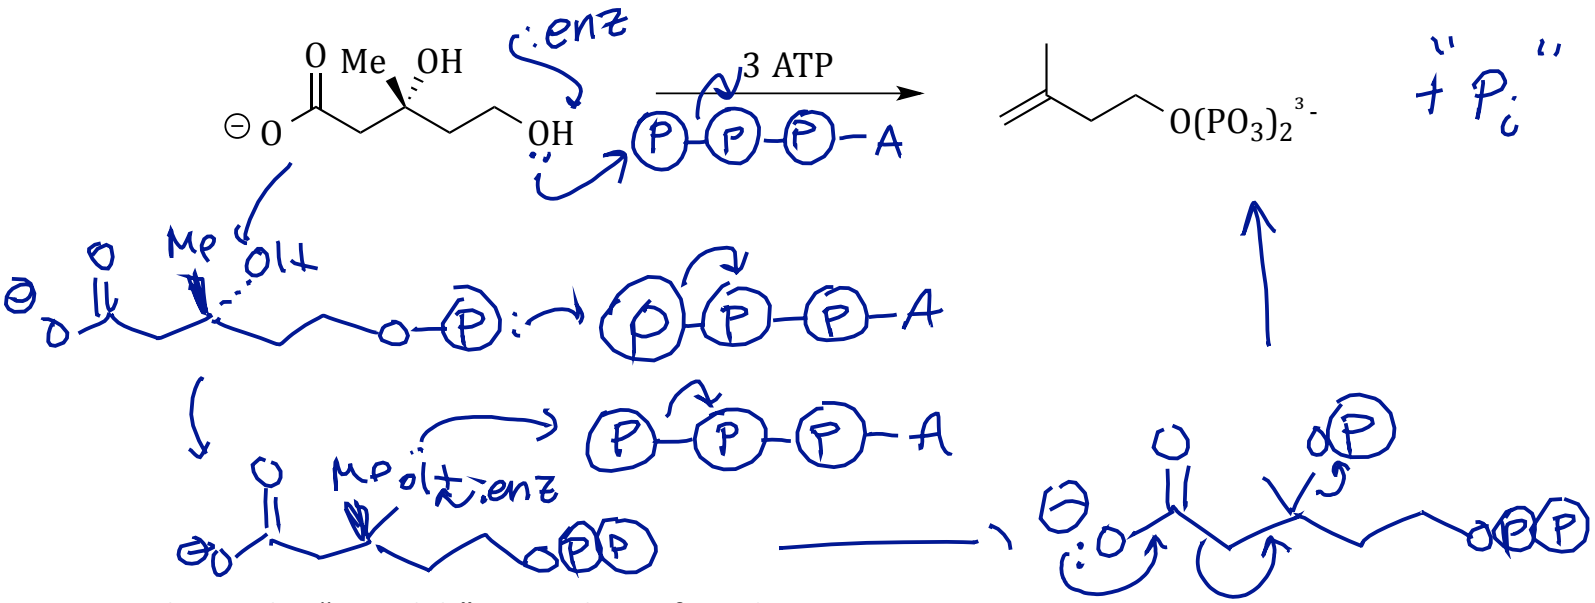
Here are the complete structures of HMG-CoA and the drug Lipitor®. What step in the reduction of HMG-CoA is blocked by the binding of Lipitor®? How can you tell?

TS mimic

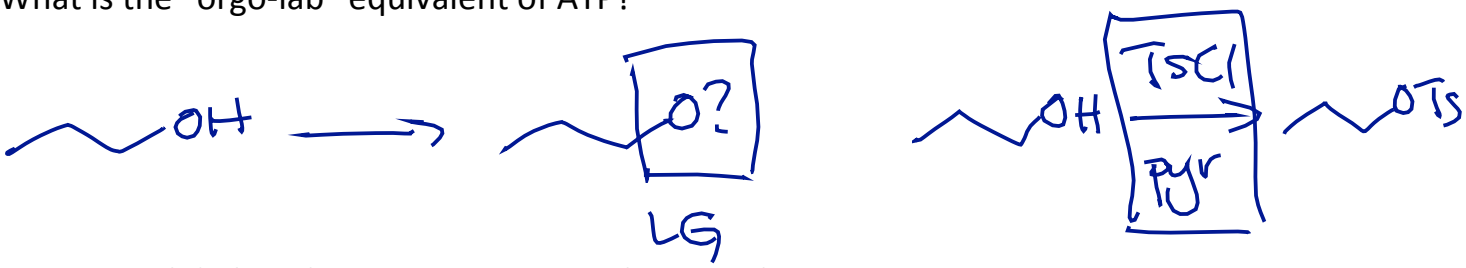


Cholesterol Biosynthesis:
3) From Mevalonate to IPP to Squalene

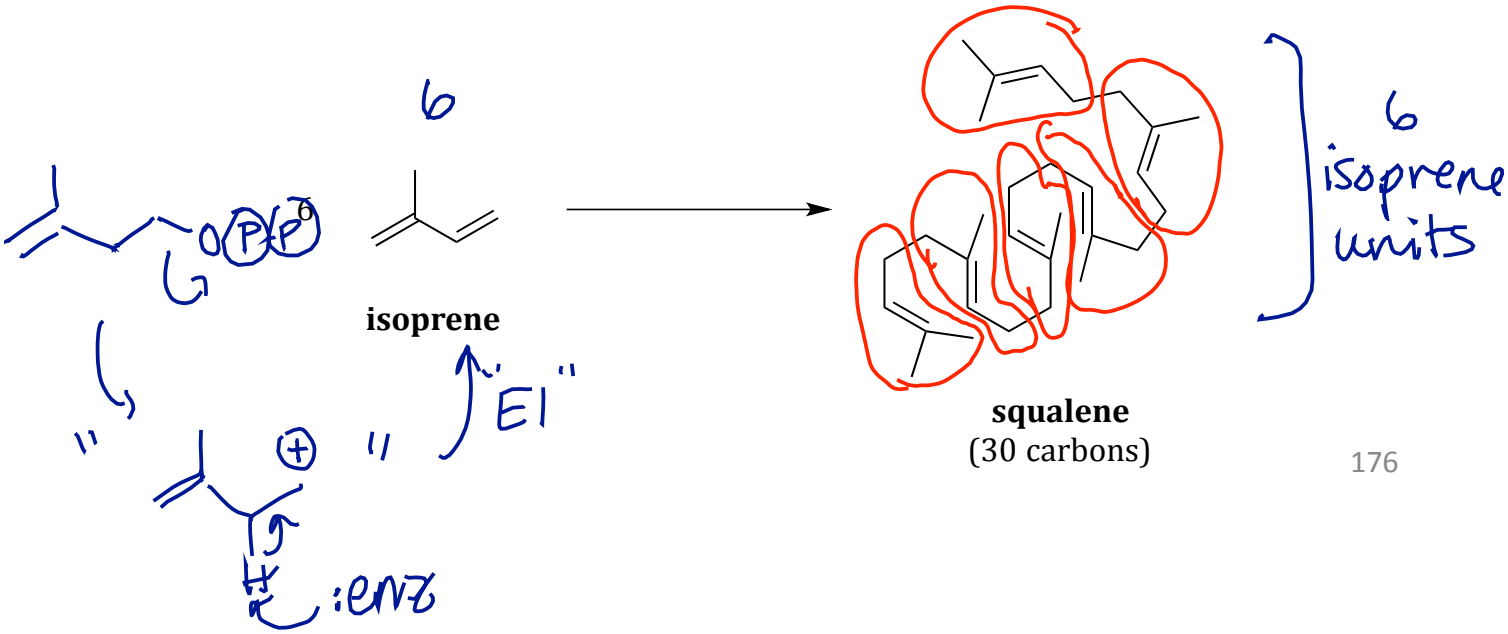
Provide a complete curved-arrow mechanism for the reaction of mevalonate with three equivalents of ATP to yield isopentenyl diphosphate



What is the "orgo-lab" equivalent of ATP?



Isopentenyl diphosphate contains a 5-carbon unit known as an *isoprene* unit. Can you see how six of these isoprene units can be joined together to form squalene?

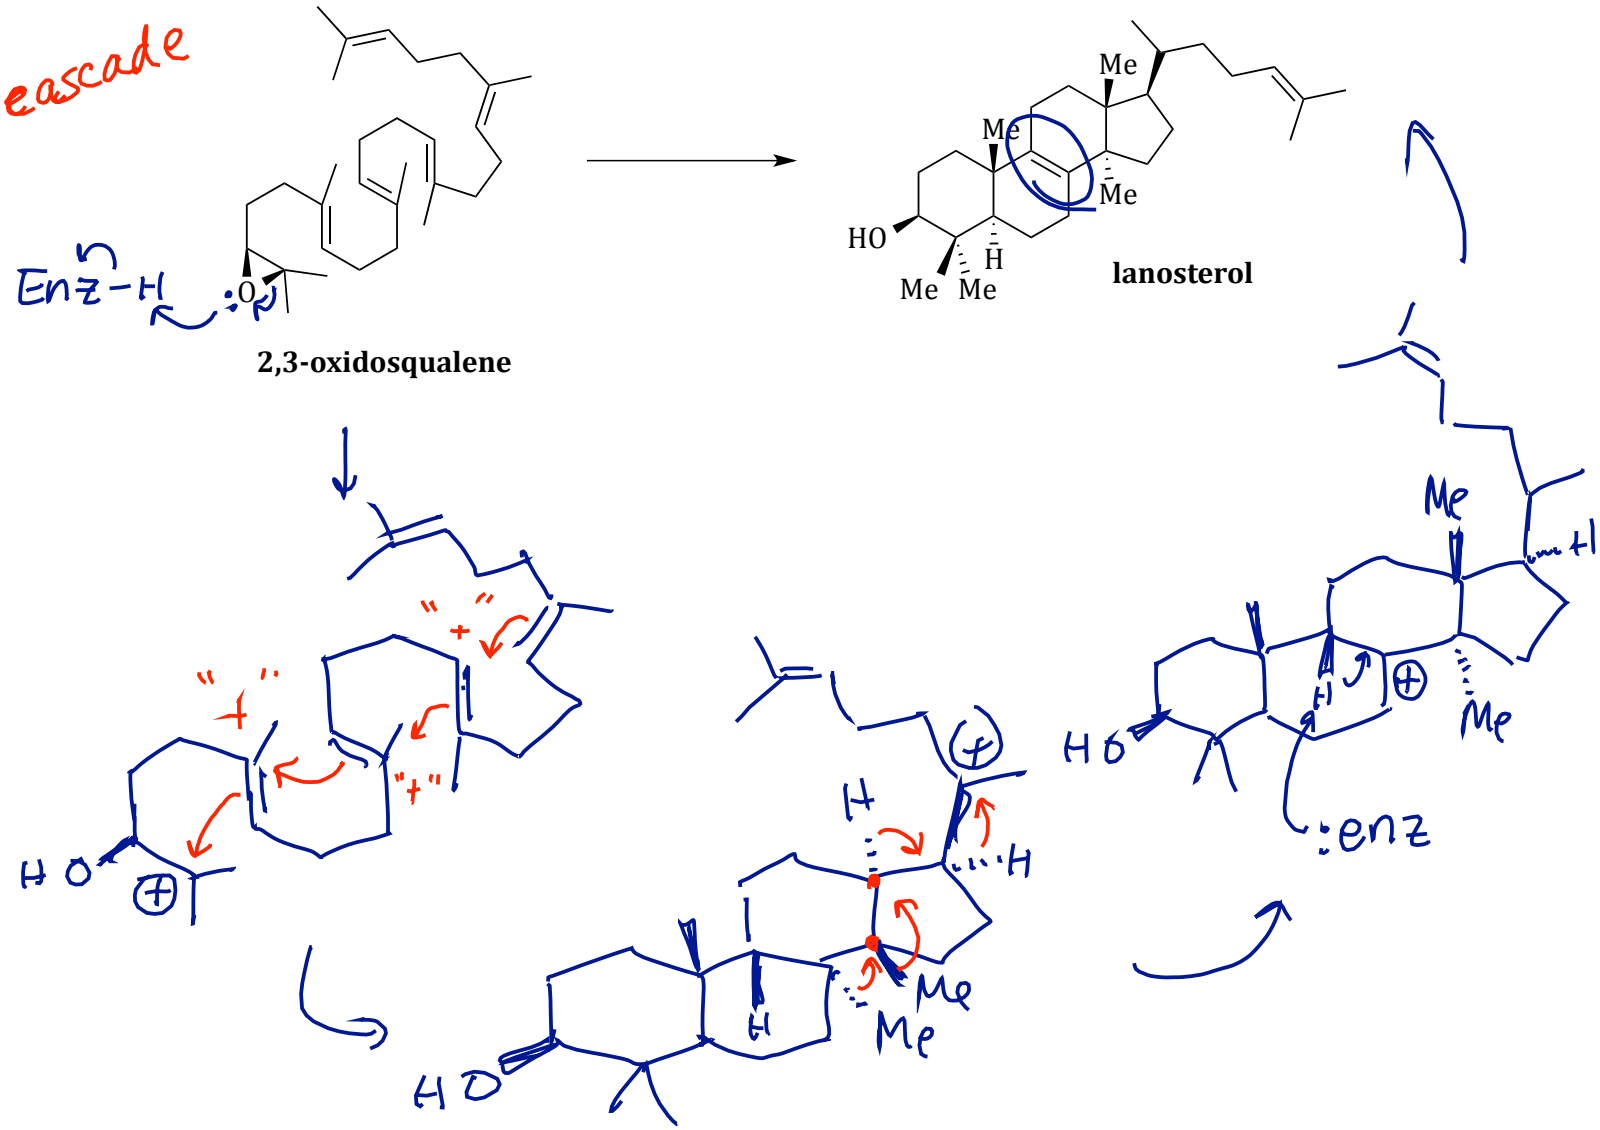


isoprene

squalene
(30 carbons)

Cholesterol Biosynthesis:
4) From Squalene to Cholesterol

Squalene is then converted to *lanosterol*. The first step is an oxidation that proceeds through a mechanism much like that of the laboratory synthesis of epoxides by peracids. Then the epoxide is opened with acid and a remarkable cascade, followed by several carbocation rearrangements, yields lanosterol in a single enzymatic step. This reaction is one of the most remarkable enzyme-catalyzed biosynthetic transformations:



Finally, lanosterol is converted into cholesterol in several further enzymatic steps….
